14. ABSTRACT: The high rate of death of ovarian cancer (OVCA) patients can be prevented if it is detected at early stage. Unfortunately, currently available traditional transvaginal ultrasound (TVUS) imaging together with serum CA-125 levels cannot detect OVCA at early stage. Malignant nuclear transformations followed by the establishment of tumor associated neo-angiogenesis are the early events in tumor development. Ovulation is an inflammatory process which exposes ovarian surface and fimbrial epithelium to inflammatory factors including interleukin 16 (IL-16). Inflammation of the ovary and tubal epithelium due to frequent ovulation leads to the development of oxidative stress and longstanding unresolved oxidative stress causes malignant transformation. Expression of IL-16 by the tumor epithelium and its serum levels has been reported to be increased during OVCA development. Thus IL-16 represents a potential marker of early OVCA which can be detected <i>in vivo</i> by ultrasound imaging provided an IL-16-targeted molecular imaging agent can be developed. The goal of this study is to develop and test the efficacy of molecular (IL-16)-targeted ultrasound (MT-U/S) imaging probe for the detection of early OVCA. This goal is being accomplished by two specific aims. Visualization of ovarian tumors in hens by TVUS improved significantly by IL-16-targeted imaging probes (Aim 1). Results obtained so far under Aim-2(Year-2 of the project life) suggest that IL-16-targeted TVUS imaging improved the detection of OVCA at early stage. Monitoring of hens continues to determine the predictability of IL-16-targeted imaging agents for early detection of OVCA.

INTRODUCTION:

Ovarian cancer (OVCA) is a fatal malignancy of women with high case-to-death ratio of patients [1]. This high rate of death can be prevented if it is detected at early stage. Unfortunately, non-specificity of symptoms at early stage and a lack of an effective early detection test, OVCA in most cases is detected at late stages when the 5-year survival rate of patients is <20% as opposed to >80% if detected at early stage [2]. Ovulation is an inflammatory process which exposes ovarian surface (site of ovulatory rupture) and fimbrial epithelium to inflammatory factors including interleukin 16 (IL-16) secreted by immune cells. Inflammation of the ovary and tubal epithelium due to frequent ovulation leads to the development of oxidative stress and longstanding unresolved oxidative stress has been suggested to cause malignant transformation. Malignant nuclear transformations followed by the establishment of tumor associated neo-angiogenesis are the early events in tumor development and progression. During malignant nuclear transformation, the shape and sizes of the nucleus undergo profound changes together with the rearrangement of nuclear matrix proteins (NMP) leading to the shedding of NMPs into the circulation. Anti-NMP antibodies are produced in response to shed NMPs [3, 4]. On the other hand, expression of IL-16 by the tumor epithelium and its serum levels increase in association with ovarian tumor development [5]. Thus IL-16 represents a potential marker of early OVCA which can be detected by ultrasound imaging provided an IL-16-targeted MT-U/S imaging agent can be developed. Approaches involving serum CA-125 levels, traditional transvaginal ultrasound (TVUS) imaging or their combination did not improve the early detection rates of OVCA. Because CA-125 is not specific for early OVCA and the traditional TVUS imaging cannot detect early OVCA due to its limited resolution [6]. Thus current detection limit of traditional TVUS imaging needs to be improved. MT-U/S can detect tumor associated changes expressed by the tumor epithelium or by the endothelium of tumor associated microvessels. The goal of this study is to develop and test the efficacy of IL-16-targeted MT-U/S imaging agent for the detection of early OVCA in association with its serum levels together with serum anti- NMP antibodies. This goal is being achieved by two specific aims. IL-16-targeted MT-U/S imaging agent was developed and tested in Aim-1. Using IL-16-targeted imaging indices established in Aim-1, hens are being monitored prospectively to detect early stage OVCA in Aim-2.

BODY: the research accomplishments associated with Task-2 outlined in the approved Statement of Work (SOW).

The hypothesis of this project is that *OVCA at early stage can be detected using molecular (IL-16) - targeted ultrasound (MT-US) imaging in association with serum IL-16 levels and anti-NMP antibodies*. The approach to test the hypothesis was to develop a tumor targeted (tumor epithelium and tumor-associated microvessels) imaging agent (IL-16) to enhance visualization of tumors and to examine its ability to detect ovarian tumors at early stage. First part of this approach: *development of IL-16-targeted TVUS imaging agent and its ability to enhance the visualization of ovarian tumors* was examined through Task-1 (Aim 1) and included in the Year-1 report submitted previously. The second part of the approach '*determine the detection ability of early stage OVCA by IL-16-targeted TVUS imaging agents in laying hens*' is being performed in Task 2 (Aim 2). The work in Year-2 (Task-2) so far been achieved are reported below:

Task 2. Determination of specificity, sensitivity and predictive values of MT-U/S imaging and serum markers diagnostic of OVCA.

2a. Selection of hens for prospective monitoring:

1. Egg rates of hens were examined and hens laying fewer eggs (low egg laying rates as an indicator of decreased ovarian function) were selected based on the prevalence of circulating anti-NMP (ovarian

nuclear matrix protein) antibodies as well as without any ovarian abnormalities detectable by IL-16-targeted TVUS imaging established in Aim-1.

2. Selected hens with (n=50 hens) or without (n=50 hens) serum anti-NMP antibodies are being monitored using IL-16-targeted TVUS imaging prospectively described in detail in subsequent sections.

2b. Scanning of hens for the detection of ovarian tumor or TAN by MT-U/S imaging and OptisonTM enhanced Doppler ultrasound imaging prospectively:

1. Selected hens were monitored and are being monitored by IL-16-targeted TVUS imaging prospectively at 15 weeks with reference to imaging indices detective of ovarian malignant transformation determined in Task 1 (Aim 1).
2. Serum samples were collected at each scan for biochemical assay including the prevalence of anti-NMP antibodies and IL-16 levels.
3. Hens indicated to have early stage ovarian cancer by IL-16-targeted TVUS imaging were sacrificed at the time of diagnosis. Gross evaluation was performed and ovarian tissues were collected and processed for routine histology, immunohistochemical, proteomic and gene expression studies. Presence of tumors and their types were determined.
4. Ovarian tissues were examined for IL-16 expression by the tumor epithelium and the endothelial cells of tumor associated microvessels as well as α -smooth muscle actin (α -SMA) expression.
5. Tissue expression and serum levels of IL-16 were confirmed by Western blotting.
6. One of the reasons of prospective monitoring of hens is to predict the time between a dormant malignant lesion and earliest TVUS detectable ovarian solid mass. Due to individual variation in tumor associated expression of IL-16, the approach is to determine the median time (in weeks) following the prevalence of serum anti-NMP antibodies and the detection of tumor. Thus the length of prospective monitoring of hens needs to be extended to additional 3 months and a request has been submitted to the sponsor for such extension.
7. The predictive value of the diagnostic indices of IL-16-targeted imaging determined in Task 1(Aim 1) will be tested at the end of the Task 2 (Aim 2).

Detailed Reports on the Accomplishments in Year-2 of the project life:

Specific Aim 2: Ovarian MT-U/S imaging indices and angiogenic indices (AI) in hens with anti-NMP antibodies will predict development of OVCA.

Animals: 3-4years old hens with low egg laying rates (<100 eggs/year) were selected from a flock of White Leghorn laying hens. Selected hens were tested for the presence of serum anti-NMP antibodies. 50 hens with anti-NMP antibodies and 50 hens without anti-NMP antibodies were selected for prospective monitoring by IL-16-targeted TVUS imaging for the detection of ovarian tumors using imaging indices established in Specific Aim 1. Hens were maintained and are being maintained in a standard poultry husbandry practices access to food and water *ad libitum*.

Serum: Blood from all selected hens were collected at each scan, serum samples were separated and stored at -80°C to determine the prevalence of anti-NMP antibodies and IL-16 levels by immunoassay later.

Molecular (IL-16) targeted ultrasound imaging and analysis of images:

Traditional ultrasound imaging (pre-targeted): Traditional transvaginal ultrasound (TVUS) imaging was performed prior to the injection of microbubbles containing IL-16-targeted imaging agents using mechanical set up reported earlier[7, 8]. Briefly, hens were held carefully by an assistant and imaging was performed using an instrument attached with a 5- to 7.5-MHz endovaginal transducer (MicroMaxx; SonoSite, Inc, Bothell, WA). Hens were immobilized, the transducer was inserted transvaginally, 2-dimensional transvaginal gray scale and pulsed Doppler sonographies were performed [7, 9]. Examination of ovarian morphology was performed by gray scale TVUS and the vascular network of the ovary were evaluated by Doppler ultrasound (DUS) imaging. Blood flow characteristics including the resistive index (RI: [systolic velocity – diastolic velocity]/systolic velocity) and the pulsatility index (PI: [systolic velocity – diastolic velocity]/mean) were automatically calculated from at least two separate Doppler images from the same ovary as reported earlier [7, 9, 10]. The lower RI and PI values are used for analysis. Images were processed and archived digitally for reviewing off-line later.

IL-16-targeted TVUS imaging:

Molecular targeted ultrasound imaging was performed following pre-targeted imaging. Hens were injected with microbubbles containing IL-16-targeted imaging agents in a similar manner with identical mechanical settings as described above. Ovarian tissues including the same area imaged during pre-targeted scanning were imaged similar to that reported earlier [8]. Microbubbles containing targeted imaging agents were observed to be accumulated in the ovary around 5-7 min from their arrival. Free unbound microbubbles were washed out. All images including still and real-time clips were archived electronically (~ 15 minutes for each hen). Visual evaluation of the effects of targeted imaging agents was performed online (during scanning) and off-line later by reviewing the archived still images and video clips. The time of targeted imaging agent arrival (interval in seconds from administration of the imaging agents to its visual observation [in seconds]) in the ovaries with or without tumor was recorded in real time. The region of interest (ROI) was selected following review of the complete clip. The average image intensity (in arbitrary values) over a ROI containing the tumor or normal ovarian stroma was calculated by computer assisted software (Microsuite™ version Five, Olympus America, Inc., Canter Valley, PA). Diagnosis of OVCA was performed on the basis of targeted ultrasound signal intensities with reference to that determined in specific aim 1. Furthermore, post-targeted RI and PI values were calculated.

Ovarian gross morphology and microscopic observation:

All hens predicted to have OVCA were sacrificed and gross pathology including presence of ovarian solid mass with or without accompanied ascites and tumor metastasis to distant organs was determined as reported earlier [11]. Gross morphology was recorded and photographed by a digital camera. Tissues were processed for routine staining to confirm the presence of tumors and their histological sub-types as reported earlier [11], immunohistochemical studies, immunoblotting as well as gene expression. Paraffin sections were also used to determine histological sub-types of ovarian tumors as well as immunohistochemical and immunoblotting studies as reported previously [11].

Immunoassay and Immunoblotting: Prevalence of anti-NMP antibodies in serum and circulating levels of IL-16 were determined by ELISA and confirmed by 1 & 2-dimensional Western blotting as reported earlier [12, 5]. Similarly, tissue expression of IL-16 was also confirmed by immunoblotting

Immunohistochemistry: Paraffin sections of ovarian tumors were used to examine IL-16 and α -smooth muscle actin (SMA)-expression by the tumor epithelium and the tumor associated microvessels as reported earlier [12, 5]. The frequencies of IL-16-expressing cells as well as microvessels expressing α -SMA and IL-16 were counted and analyzed as reported previously [12, 5]

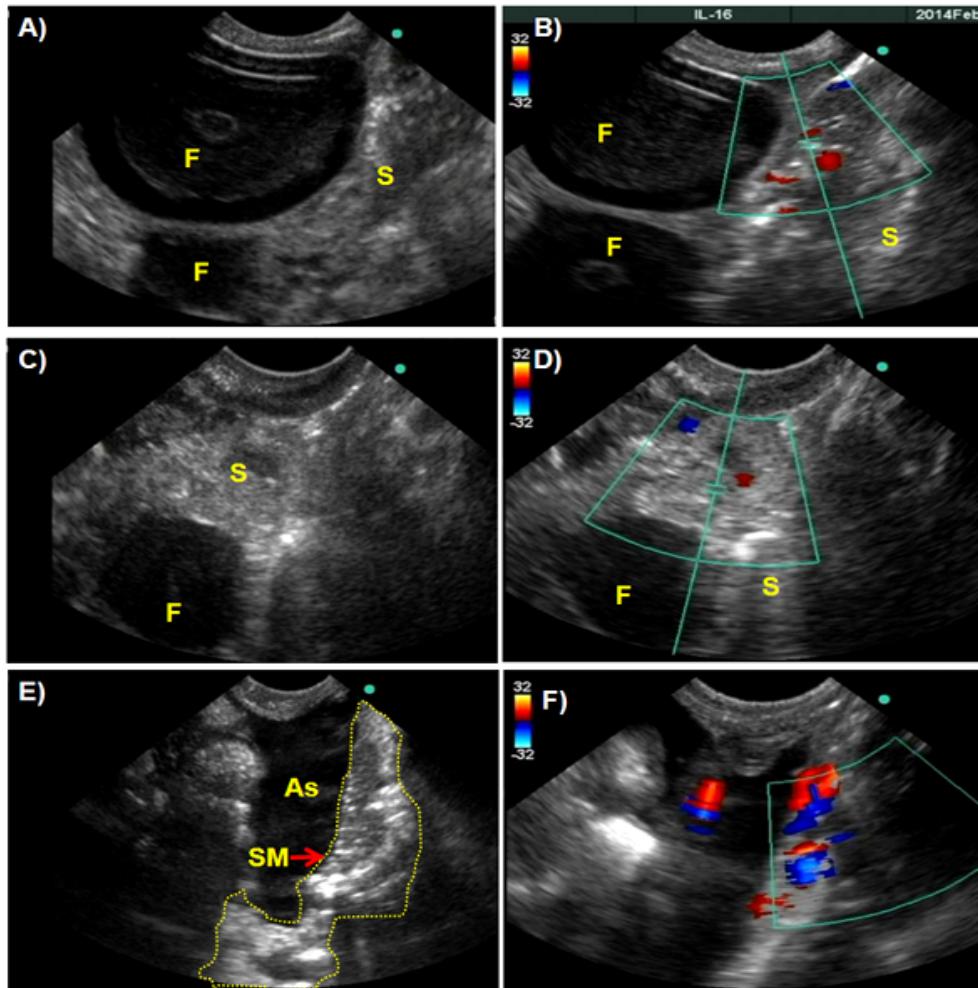

Figure X: Changes in ovarian morphology leading to tumor development in hens detected by prospective IL-16-targeted molecular ultrasound imaging. **A-B)** Gray scale and Doppler sonogram of a hen ovary at 1st scan showing two developing preovulatory follicles (F) in the stroma (S). No abnormality was detected in gray scale ovarian morphology and in ovarian vasculature by Doppler ultrasound scan. **C-D)** At 2nd scan (30 weeks after) no remarkable change was observed in the same ovary by gray scale and Doppler sonography except the number of follicles. Compared with 1st scan, the number of developing follicle decreased as the hen ages. **E-F)** The hen presented in 1st and 2nd scan developed solid mass (SM) and detected by targeted imaging at 3rd scan. Compared with 1st and 2nd scan, more microvessels were detected during 3rd scan by Doppler imaging suggesting tumor associated changes in ovarian blood flow. As=Ascites.

Results:

Development of tumor associated changes in the ovary and its detection by prospective monitoring using IL-16-targeted TVUS imaging:

Ovaries in hens with serum anti-NMP antibodies had one or two preovulatory follicles without any abnormal solid mass during at first scan after 15-weeks from the start of the prospective scanning (**Figure 1A-B**). Similarly, remarkable changes in Doppler indices indicative of tumor associated blood flow characteristics were also not observed. In addition, significant increase in serum IL-16 levels was also not recorded. Compared with first scan, serum levels of IL-16 increased at second scan after 30 weeks from initial scan in 11 of 50 hens with anti-NMP antibodies. Compared with 1st scan, significant increase in the intensity of IL-16-targeted imaging was recorded in these hens at second scan after 30 weeks (**Figure 1C-D**). However, tumor associated changes in ovarian morphology were not observed. After 45 weeks from initial scan (3rd scan), tumor associated changes in ovarian morphology including high intensity of IL-16-targeted imaging (**Figure 1E-F**), serum IL-16 levels and Doppler

indices were observed in 11 hens (Figure 1F). Targeted imaging also showed presence ascites-like fluids in few of these hens (3). All these hens were considered to have OVCA.

Gross morphology and microscopic examinations of hens suggested to have ovarian tumors by targeted imaging:

All hens predicted to have ovarian tumors by IL-16-targeted TVUS imaging were sacrificed after imaging. Ovarian gross morphology examined, photographed and compared with ultrasound imaging predictions. Presence of solid tumor mass in the ovary, degree of tumor metastasis, stages of OVCA and accompanying ascites (if any) was recorded. Ovaries with tumor and oviducts were collected,

processed for paraffin, frozen, proteomic and molecular biological studies. Routine microscopic examination with hematoxylin-eosin staining were performed to confirm sub-types of ovarian tumors (Figure 2) as reported earlier [11]. Gross and histological examinations revealed adenocarcinoma of the ovary and confirmed the predictions of IL-16-targeted TVUS imaging. Of 11 hens, 9 hens had tumors limited to the ovaries (early stage) and 2 hens had tumors metastasized to other organs associated with ascites.

Determination of serum IL-16 levels:

All serum samples collected during prospective scans were examined for IL-16 levels and changes in its level in association with OVCA development were examined. Serum levels of IL-16 were determined using Chicken IL-16 Vetset™ ELISA Kit (Kingfisher Biotech, St. Paul, MN) pre-coated with anti-Chicken IL-

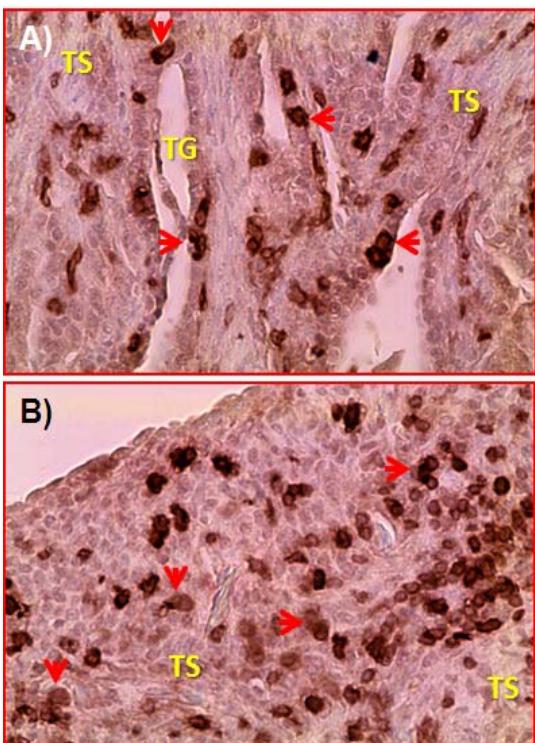

Figure 3. Changes in the population of IL-16 expressing cells in association with ovarian cancer (OVCA) development in hens. A) Section of a well-developed ovarian adenocarcinoma showing IL-16 expression by malignant epithelium and stromal cells. B) Section of a poorly differentiated ovarian adenocarcinoma showing many IL-expressing cells. TG=tumor gland, TS=tumor stroma, Red arrows are the examples of IL-expressing cells. 40X

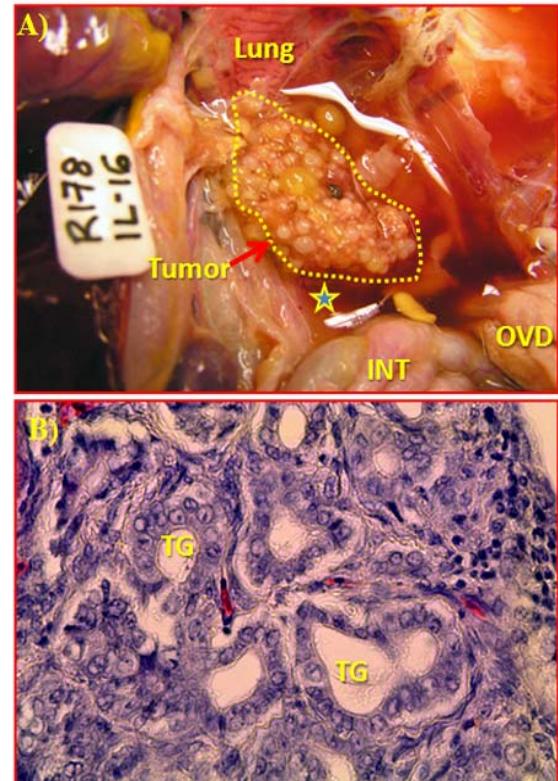

Figure 2: Ovarian tumors at early stage in a hen detected by IL-16-targeted molecular ultrasound imaging presented in *figure 1*. A) Gross presentation of the tumor showing the solid mass limited to the ovary accompanied with little ascites. No metastasis is seen to the other organs including oviduct (OVD) and intestine (INT). B) Routine staining (hematoxylin and eosin) and microscopic examination confirmed the mass is an adenocarcinoma of the ovary. TG=tumor gland. 40X

16 antibodies and chicken IL-16 as standards as per the manufacturer's instructions reported earlier and as reported previously [5]. Serum IL-16 levels in hens increased in association with ovarian tumor development. Significant increase in serum IL-16 levels was detected in hens with early stage OVCA which increased further in hens at late stages of OVCA.

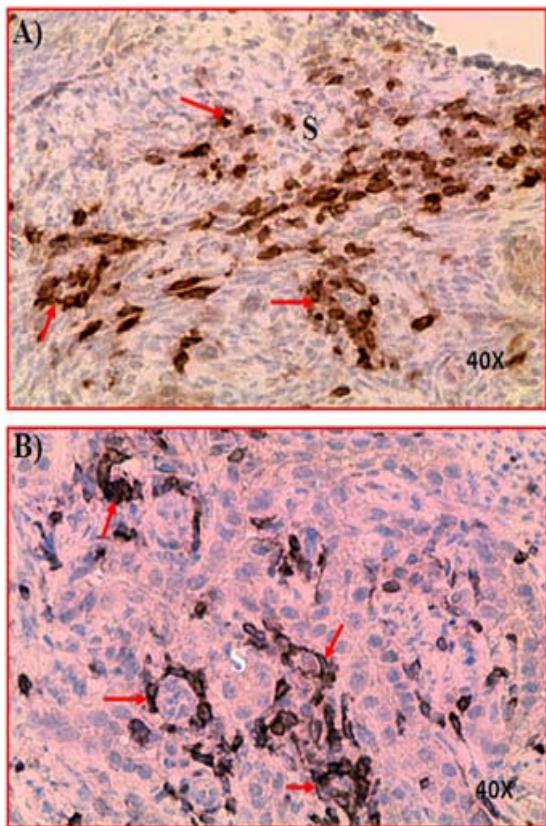

Figure 4: Ovarian tumor associated expression of IL-16 by microvessels in hens with OVCA detected by IL-16-targeted molecular ultrasound imaging. A) Section of an ovary with early stage OVCA. Endothelial cells of microvessels seen stained for IL-16. B) Section of late stage ovarian tumor. More microvessels are seen to express IL-16 in the tumor stroma (S). IL-16 expressing microvessels appeared leaky and surrounded by incomplete endothelial layer. Arrows indicate examples of IL-16 – expressing microvessels. 40X

progression. Moreover, increased tissue expression of IL-16 might also a reason of increased signal intensity of IL-16-targeted ultrasound imaging as compared with pre-targeted imaging.

Detection of IL-16 expression by ovarian tumors and ovarian tumor associated microvessels:

Tissue expression of IL-16 was examined immunohistochemically. Malignant cells in OVCA hens stained for IL-16 (**Figure 3A**). In ovaries with tumor at early stage, many stromal cells including immune cells were positive for IL-16 expression. Compared with well developed tumors, IL-16 expression by the tumor cells were remarkably high in poorly developed tumors (**Figure 3A-B**). The population of IL-16 expressing cells increased further in tumors at late stage. For the first time, this study has shown the expression of IL-16 by the endothelium of tumor associated microvessels (**Figure 4**). The population of IL-16 expressing microvessels increased as the tumor progressed to late stages.

Thus, as reported earlier, increased expression of IL-16 by malignant cells, stromal cells as well as endothelial cells of microvessels might be the reasons of increased serum IL-16 levels in hens associated with ovarian malignant development and progression.

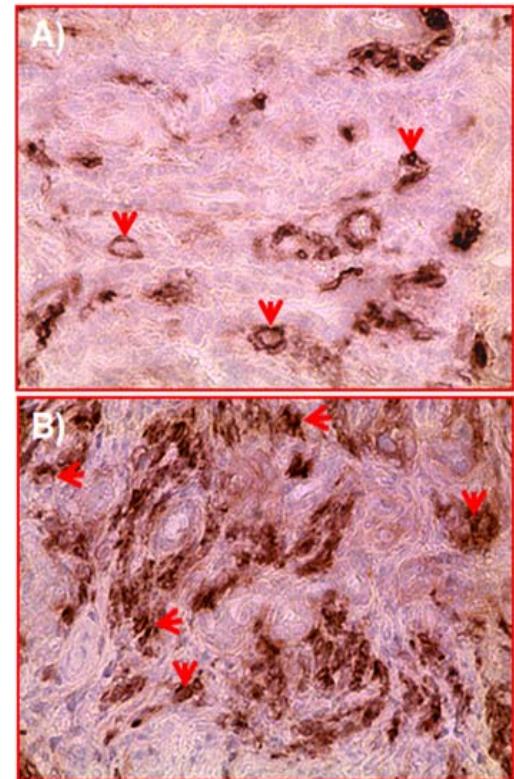

Figure 5. Changes in the expression of α -smooth muscle actin (α -SMA) by tumor associated microvessels in hen ovary during OVCA development. A) Tumor associated microvessels expressing α -SMA were localized in the stroma of a well-developed ovarian adenocarcinoma. B) Expression of α -SMA was intense in a poorly differentiated ovarian adenocarcinoma. Arrows are the examples of α -SMA expressing vessels in the stroma of ovarian tumors. 40X.

Detection of α -SMA expressing microvessels:

Tumor associated neo-angiogenesis is one of the earlier events in OVCA development and progression. The population of α -SMA-expressing microvessels was determined by immunohistochemistry as reported earlier [5]. The frequency of α -SMA-expressing microvessels increased remarkably in association with OVCA development and progression (**Figure 5**). Increased population of microvessels might be involved in increased blood flow to the growing tumor and thus are associated with lower RI and PI values in tumor hens as observed by the Doppler sonogram (**Figure 1E**).

Detection of anti-NMP antibodies in serum of hens during prospective monitoring: Serum samples collected at different scan intervals were tested for the presence of anti-NMP antibodies using NMPs from archived ovarian tumor NMPs collected in Aim 1. Collection of NMPs and detection of anti-NMP antibodies by immunoassay were performed as reported earlier [4, 13, 12]. Briefly, 96-well ELISA plates (NUNC) were coated with tumor NMPs and the immunoreactivities of serum samples from each hen collected at different scanning intervals were tested against the coated tumor NMPs. Each serum sample was assayed in duplicate and the plates were read at 405nm in an ELISA plate reader (Softmax Pro, version 1.2.0, software; Molecular Devices, Sunnyvale, CA). Serum from normal hens with fully functional ovaries was used as negative control (established in earlier studies) for the presence of anti-NMP antibodies. Serum with optical density (OD) values higher than the control mean + 2SD (cut-off value) were considered positive for the presence of anti-NMP antibodies.

All hens positive for serum anti-NMP antibodies during initial scan remained positive throughout the prospective scanning completed so far. Hens with apparently normal ovaries are currently under monitoring. Representative serum samples with positive reactivity against tumor NMPs were analyzed by immunoproteomic study (2 dimensional-Western blotting, 2D-WB) to confirm immunoreactivities observed in ELISA. Immunoreactive NMPs of different sizes with a dense band at approx. 30-100kDa were detected by 2D-WB (**Figure 6**) confirming the results of ELISA for the prevalence of anti-NMP antibodies in serum.

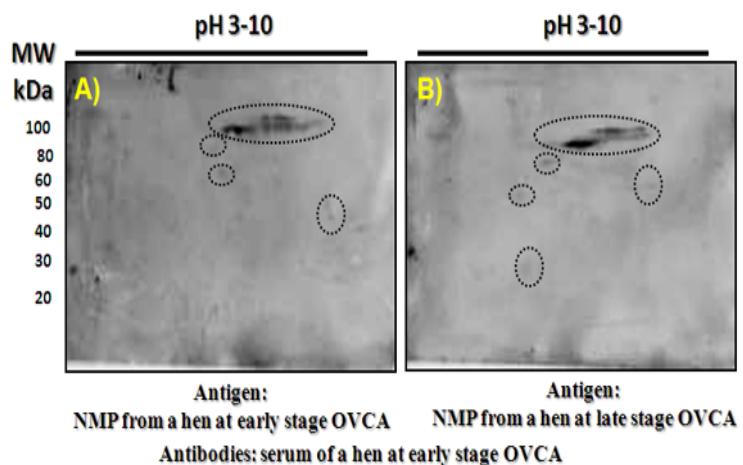

Figure 6. Detection of serum prevalence of anti-NMP antibodies in hens. Serum from a hen at early stage OVCA detected by IL-16-targeted molecular ultrasound imaging were examined against NMPs from heterogenous ovarian tumors **A**) at early stage and **B**) at late stage. Nuclear matrix proteins (NMPs) were resolved and separated according to their molecular weight (MW) and pH and immunoblotted by 2dimensional Western blotting, 2D-WB. The same OVCA serum reacted in similar patterns against the NMPs from early and late stage OVCA. Serum from OVCA hens specifically detected ovarian NMPs of 30-100kDa. These results suggest that malignant nuclear transformation is associated with the prevalence of anti-NMP antibodies in serum.

KEY RESEARCH ACCOMPLISHMENTS IN YEAR 2 AND WORKS REMAINING TO BE COMPLETED:

- IL-16-targeted imaging agents bounded with their targets in ovary. The results so far obtained confirmed the observation of Aim-1 that IL-16-targeted imaging agents enhance ovarian tumor detection at early stage.
- Serum levels of IL-16 increase in relation to tumor associated enhanced tissue expression of IL-16.
- Malignant nuclear transformation (as indicated by the prevalence of anti-NMP antibodies in serum) and serum IL-16 levels may differentiate hens destined to develop OVCA later from non-OVCA hens.
- Expression of IL-16 by tumor associated microvessels is a noble finding of this study. Thus, IL-16-expressing microvessels can be targeted to inhibit tumor associated neoangiogenesis and OVCA progression.
- Determination of overall predictability of IL-16-targeted imaging agents in detecting early stage OVCA needs to allow the development of OVCA in most of the hens with serum anti-NMP antibodies group. Thus prospective monitoring of hens needs to be continued further for additional 12 weeks.
- One of the important information required for screening for OVCA is the time needed for hens with serum anti-NMP antibodies to develop a solid mass detectable by IL-16-targeted imaging. This time of incidence of solid mass in the ovary should be the median (incidence of OVCA in most of the hens) in weeks/months. This information will lead to the suitability of these markers for a screening protocol to detect early stage OVCA in clinical setting. Therefore, to determine the median time of first OVCA incidence detectable by the targeted imaging, the remaining hens with serum anti-NMP antibodies need to be monitored further for another 12 weeks.

REPORTABLE OUTCOMES DURING YEAR-2:

Manuscript # 2 is under preparation.

CONCLUSIONS:

With the completion of Year 2, part of the results so far obtained suggest that compared with non-targeted traditional TVUS scanning, IL-16-targeted imaging agents enhanced ultrasound signals and improved the detection of ovarian tumors at early stage in hens. The enhancement of signal intensities by targeted imaging agents was due to their bindings with targets in the ovary. This enhancement in signal intensities was associated with increased expression of IL-16 by the ovarian malignant cells, stromal cells as well as by tumor associated microvessels. Serum levels of IL-16 increased in association with malignant transformation in the ovary. Similarly, results on anti-NMP antibodies confirmed that anti-NMP antibodies become prevalent before the tumor becomes detectable by ultrasound-imaging. With the completion of proposed extended monitoring period current results will be further confirmed and the feasibility of IL-16-targeted imaging agents and serum markers for the early detection of OVCA will be determined.

17 June 2014

Dear Dr. Barua,

The Planning Committee for the 10th Biennial Ovarian Cancer Research Symposium has conducted a thorough review of nearly 190 submitted abstracts. We are pleased to notify you that your abstract entitled "Contrast enhanced interleukin 16 targeted imaging detects ovarian tumor at early stage" has been selected for oral presentation in the scientific session "Strategies for Controlling Ovarian Cancer". The Symposium will take place on Monday and Tuesday, September 8-9, 2014 in Seattle, Washington.

If you would like to accept our invitation, please complete and return the attached forms to me via email by Monday, June 30th, 2014. The Symposium is an accredited activity by the Accreditation Council for Continuing Medical Education (ACCME), and all speakers must provide the requested information. Also contained in the attached PDF are details concerning your participation including the deadline for submitting your presentation as well as the travel stipend being offered to you, which is intended to help defray costs, but may not entirely cover your expenses.

It is our pleasure to waive the Symposium registration fee. You do not need to register yourself online as we will automatically register you if you accept our invitation.

If you have any questions, please contact me at (206) 215-2964 or Wendy.Law@swedish.org. On behalf of the Rivkin Center, Swedish Medical Center, and the American Association for Cancer Research, we would like to express our enthusiasm about your research and hope to see you in Seattle this September!

Best Wishes,

Contrast enhanced interleukin 16 targeted imaging detects ovarian tumor at early stage

Animesh Barua¹, Aparna Yellapa¹, Pincas Bitterman¹, Janice M Bahr², Sanjib Basu¹, Sameer Sharma¹ and Jacques S. Abramowicz^{1,3}

¹Rush University Medical Center, Chicago and ²University of Illinois at Urbana-Champaign, IL, ³Wayne State University, Detroit, MI

Background: The high rate of death of ovarian cancer (OVCA) patients can be reduced if it is detected at early stage. Neither suggested serum markers nor the currently available traditional transvaginal ultrasound (TVUS) imaging or their combinations can detect OVCA at early stage. No imaging target in the ovary for TVUS imaging corresponding to the suggested serum markers has been defined. Moreover, due to the limited resolution, TVUS imaging cannot detect OVCA at early stage. Thus, new imaging target(s) together with improvement in resolution is necessary for early OVCA detection by TVUS imaging. Interleukin 16 (IL-16), a proinflammatory cytokine, associated with longstanding unresolved inflammation due to frequent ovulation, has been reported to be increased during OVCA development. IL-16 is expressed by the ovarian malignant cells and tumor associated neoangiogenic (TAN) microvessels. Thus IL-16 represents a potential marker of early OVCA which can be detected *in vivo* by TVUS imaging provided a molecular targeted contrast enhanced imaging agent can be developed.

Objective: The goal of this study was to develop and test the efficacy of molecular (IL-16)-targeted ultrasound imaging probe for the detection of early OVCA.

Materials and Methods: 3-years old (n=150) White Leghorn laying hens with normal or low egg laying rates or stopped-egg laying were scanned by TVUS before and after intravenous injection with IL-16-targeted microbubbles. IL-16-targeted imaging agents were prepared by conjugating anti-chicken IL-16 antibodies with Targetster® containing microbubbles (Targeson Inc, San Diego). All images were archived and analyzed offline. Serum samples were collected, hens were euthanized, ovarian tissues were processed for paraffin or frozen sections and nuclear matrix protein (NMP) extraction. Ovarian tumors were confirmed by gross morphology and routine histology. Sera were tested for anti-NMP antibodies (a marker of malignant nuclear transformation) and IL-16 levels by immunoassay and 1- & 2D-Western blot (WB). The frequencies of IL-16 expressing cells were determined by immunohistochemistry (IHC).

Results: IL-16-targeted microbubbles bounded with ovarian tumors and appeared as shining mass of irregular-shape. Compared with non-targeted, IL-16-targeted imaging increased the visualization of ovarian tumors remarkably. All hens with suspected tumor mass (n=23, 7 early and 16 late stages) were detected by IL-16-targeted imaging and confirmed by gross examination. The frequency of IL-16 expressing cells detected by IHC confirmed the prediction of targeted ultrasound imaging. Serum levels of IL-16 were higher in OVCA hens than in normal hens and correlated with the frequencies of IL-16 expressing cells and ovarian TAN vessels. Prevalence of anti-NMP antibodies were not detected in normal hens while all hens with OVCA were positive. Immunoreactive tumor antigens (NMPs) of 50-80kDa were detected by 2D-WB.

Conclusion: IL-16-targeted ultrasound imaging enhanced the visualization of ovarian tumors remarkably. The enhanced intensity of IL-16-targeted imaging was correlated with serum IL-16 levels and the prevalence of anti-NMP antibodies. Thus, IL-16-targeted imaging in association with serum anti-NMP antibodies may improve OVCA detection at early stage. These results will form a foundation for a clinical study. *Support:* Dept. of Defense award # W81XWH-12-1-0460.

tation protection against environmental toxins. In parallel, PIF enhances trophoblast invasion balancing TIMP/integrin ratio as well up-regulating trophoblastic pro-tolerance HLA-G expression. Finally, *in vivo* PIF administration maximizes the number of implantation sites that successfully reach the fetal stage (murine). Collective data corroborates that PIF-initiated maternal recognition orchestrates maternal adaptation that is required for successful pregnancy outcome.

IL-33-responsive group 2 innate lymphoid cells are present in mouse uterine tissue and may play roles in healthy pregnancy

KR Bartemes¹, H Kita²

¹Department of Immunology, Mayo Clinic, MN, USA; ²Department of Medicine, Mayo Clinic, MN, USA

Problem: Group 2 innate lymphoid cells (ILC2s) that are responsive to IL-33 drive helminth immunity, type 2 immune responses, and tissue pathology and homeostasis in mucosal organs, such as lungs and skin. Considering their biological effects, ILC2s may also play a role in the placenta and be involved in fetus-protective type 2 immunity. Indeed, recent reports have implicated changes in levels of both IL-33 and soluble IL-33 receptor (i.e. sST2) in spontaneous abortion and pre-eclampsia. Here, we sought to examine the presence of ILC2s in uterine tissue and investigate the effects of ST2 deficiency on successful pregnancy outcomes in mice.

Methods of study: Single cell suspensions of murine uteri were examined by flow cytometry for the presence of ILC2s. Dynamic changes in ILC2s in uteri were examined in IL-5-reporter mice by administering IL-33 systemically. To examine the role of IL-33/ST2 signaling in healthy pregnancy, ST2^{-/-} females (on a Balb/c background) were mated with ST2^{-/-}, MHC-matched Balb/c and MHC-mismatched C57B6 males. Balb/c, C57B6 and Balb/c × C57B6 pairs were used as controls. Litter sizes and numbers of non-viable pups (survival less than 24 hr) were examined.

Results: Lineage-negative, CD25⁺ and CD44⁺ ILC2s were found in normal murine uteri. Systemic administration of IL-33 to naïve Balb/c mice increased the ILC2 numbers in uteri and induced IL-

5 production by them *in vivo*, suggesting that IL-33 affects the number and activity of uterine ILC2s. Litter sizes were not significantly different among the pairings irrespectively of their genotypes. However, total numbers of non-viable pups, percent of litters with at least one non-viable pup and percent of non-viable pups per litter were significantly increased in ST2^{-/-} × C57B6 pairs when compared to control pairs.

Conclusion: IL-33-responsive ILC2s are present in murine uterine tissue and may play pivotal roles in successful reproduction.

Interleukin-16 enhances ovarian tumor associated neoangiogenesis

A Yellapa, JM Bahr, S Grasso, S Sharma, A Barua

Rush University Medical Center, Chicago University of Illinois at Urbana-Champaign, IL, USA

Problems: Ovarian cancer (OVCA), a lethal malignancy of women, disseminates locally in the peritoneal cavity. Tumor microenvironment plays important roles in OVCA metastasis. Tumor associated neo-angiogenesis (TAN) is a hallmark of OVCA progression and cytokines may stimulate the establishment of early TAN. Interleukin (IL)-16, a pro-inflammatory cytokine is associated with OVCA development. The goal of this study was to examine whether IL-16 stimulates ovarian TAN during OVCA development.

Method of study: Four years old White Leghorn laying hens with ($n = 17$) or without ($n = 20$) ovarian tumors were selected by ultrasound scanning and OVCA stages was determined following euthanasia. Ovarian tissues and serum samples from hens were processed for immunoassay, immunohistochemistry (IHC), proteomic and gene expression studies for IL-16 and SMA-expressing micro vessels. Normal ovarian epithelial cells were treated with IL-16 to determine expression of IL-8, an angiogenic factor. HUVEC cells were examined for CD9 (receptor for IL-16) expression. Differences in IL-16 expression and micro vessel frequencies among normal and OVCA hens were determined by one-way ANOVA and paired T-tests.

Results: OVCA were limited to the ovaries in eight hens (early stage) and metastasized in nine hens (late stage). IL-16 expression was significantly

($P < 0.01$) high in hens with early stage OVCA and increased further in late stage OVCA. Frequency of SMA-expressing micro vessels were significantly ($P < 0.001$) high in OVCA hens than normal hens. Increase in IL-16 expression in OVCA hens was positively correlated with the frequencies of SMA-expressing micro vessels. A strong band for IL-8 was detected in IL-16 treated cells and HUVAC cells expressed CD9 proteins.

Conclusion: The results suggest that changes in IL-16 expression were associated with increased frequency of SMA-expressing micro vessels. IL-16 enhanced expression of IL-8, possibly through its receptor CD9. These results suggest a novel role of IL-16 and may be useful in designing antitumor immune therapeutics targeting IL-16 for OVCA prevention.

Chorioamnionitis induced by inactivated group B streptococcus: from placental lesions to autism spectrum disorders features

JD Bergeron¹, ME Brochu¹, C Guiraut¹, LC Fortier², C Poyart³, G Sébire¹

¹Department of pediatrics, Université de Sherbrooke & McGill University, Canada; ²Department of microbiology, Université de Sherbrooke, Canada; ³Institut Cochin, Université de Paris, France

Problem: A high incidence of neurobehavioral disorders, such as autism spectrum disorders, occurs in children born to mothers who experienced infections during pregnancy. According to our hypothesis group B streptococcus (GBS) induced maternal immune activation plays a role in placental lesions and offspring subsequent neurobehavioral disabilities.

Methods of study: We designed a new pre-clinical animal model in which dams were injected every 12 hr with inactivated GBS (109 CFU) from serotype 1a GBS, versus saline, from gestational day (G) 19 to G22. Some dams gave birth naturally at G23 (behavioral studies with pups) and C-sections were performed at G22 on other dams to remove placentas for immunohistochemical studies and proteins analysis.

Results: GBS-exposed placentas presented cystic lesions and polymorphonuclear infiltration located within the decidual/maternal side of the placenta. Interestingly, preliminary results showed higher

level of PMN infiltration and expression of MMP8 in placentas associated with male than those associated with female fetuses. Surprisingly, cardinal features of human autism were found predominantly in males, characterized mainly by social interactions impairments, lack of exploratory behavior and singular sensory processing.

Conclusions: Our results show for the first time that materno-fetal inflammatory response to GBS plays a role in the induction of placental insults and neurobehavioral disabilities in offspring. Placental lesions and changes in placental proteins may spread through a fetal inflammatory reaction syndrome (FIRS) affecting developmental processes of the offspring's brain, thereby increasing its susceptibility to ASD, especially for males.

Distinct microRNA and their putative target mRNA expression in endometrial lymphocytes, endometrium and trophoblast during healthy and abortive porcine pregnancy

M Bidarimath¹, AK Edwards¹, JM Wessels², K Khalaj^{1,2}, RT Kridli^{2,3}, C Tayade^{1,2}

¹Department of Biomedical and Molecular Sciences, Queen's University, Kingston, ON, Canada; ²Department of Biomedical Sciences, Ontario Veterinary College, University of Guelph, Guelph, Ontario, Canada; ³Department of Animal Production, Faculty of Agriculture, Jordan University of Science and Technology, Irbid, Jordan

Problem: Approximately 25–40% genetically normal conceptuses are spontaneously lost during peri-attachment and mid-pregnancy in pigs. A deficit in vasculature is one of the major factors associated with conceptus loss. During early pregnancy, endometrial lymphocytes are uniquely recruited to the maternal-fetal interface by conceptus derived signals. They adopt a specialized phenotype that regulates placental angiogenesis but precise mechanism is not known. microRNAs are emerging as bio-regulatory molecules of various processes including angiogenesis. We hypothesize that microRNAs are involved in development of endometrial lymphocytes and their angiogenic functions at the maternal-fetal interface.

Methods of study: Laser capture micro dissected endometrial lymphocytes, endometrium, and trophoblasts associated with healthy and spontaneously

32 **Abstract**

33 Limited resolution of transvaginal ultrasound (TVUS) scanning is a significant barrier to early
34 detection of ovarian cancer (OVCA). Contrast agents have been suggested to improve the
35 resolution of TVUS scanning. Emerging evidence suggests that expression of interleukin 16 (IL-
36 16) by the tumor epithelium and microvessels increase in association with OVCA development
37 and offers a potential target for early OVCA detection. The goal of this study was to examine the
38 feasibility of IL-16-targeted contrast agents in enhancing the intensity of ultrasound imaging
39 from ovarian tumors in hens, a model of spontaneous OVCA. Contrast agents were developed by
40 conjugating biotinylated anti-IL-16 antibodies with streptavidin coated microbubbles.
41 Enhancement of ultrasound signal intensity was determined pre-and-post-injection of contrast
42 agents. Following scanning, ovarian tissues were processed for the detection of IL-16-expressing
43 cells and microvessels. Compared with pre-contrast, contrast imaging enhanced ultrasound signal
44 intensity significantly in OVCA hens at early ($P < 0.05$) and late stages ($P < 0.001$). Higher
45 intensities of ultrasound signals in OVCA hens were associated with increased frequencies of IL-
46 16-expressing cells and microvessels. These results suggest that IL-16-targeted contrast agents
47 improve the visualization of ovarian tumors. The laying hen may be a suitable model to test new
48 imaging agents and develop targeted anti-OVCA therapeutics.

51

52

53

54

55 **1. Introduction**

56 The global yearly rate of death of women due to ovarian cancer (OVCA) is approximately 140,
57 200 women and that of the USA is approximately 15,000[1, 2] making OVCA one of the lethal
58 gynecological malignancies. Because of the lack of an effective early detection test, OVCA in
59 most cases is detected at late stages. Development of resistance to currently available
60 chemotherapeutics and frequent recurrences when detected at late stages decrease 5-year survival
61 rate of OVCA patients to <20%. In contrast, OVCA can be cured in >90% cases when it is
62 detected at early stage. Therefore, early detection of OVCA is crucial and an effective early
63 detection test is urgently needed. Serum levels of CA-125 alone or in combination with
64 traditional transvaginal ultrasound (TVUS) imaging is the currently available test for the
65 detection of OVCA [3]. However, neither the CA-125 nor the TVUS can detect OVCA at early
66 stage specifically as serum CA-125 level is elevated in patients with several benign
67 gynecological as well as non-gynecological abnormalities. On the other hand, although TVUS is
68 the currently available preferred method for non-invasive imaging of ovarian abnormalities,
69 unfortunately, with its limited resolution, traditional TVUS cannot detect OVCA at early stage
70 [4]. In addition, a combination of serum CA-125 levels together with traditional TVUS imaging
71 also failed to detect early OVCA as no imaging target in the ovary corresponding to the elevated
72 serum CA-125 levels is established [4]. Thus a fresh approach is needed.

73 Extensive studies have been performed on the establishment of serum biomarkers for the
74 detection of OVCA at early stage and a plethora of serum based marker(s) have been suggested.
75 However, due to their lack of specificity and sensitivity, none of these markers was successful in
76 detecting OVCA at early stage indicating that serum marker(s) alone may not be able to detect
77 OVCA at early stage. Thus, an imaging target related to the malignant transformation of the

78 ovary needs to be established and the current detection limit of traditional TVUS needs to be
79 enhanced to detect early OVCA-related changes in the ovary. Moreover, to facilitate early
80 detection of OVCA specifically, this imaging target(s) should also be associated with a surrogate
81 marker(s) to be detectable in the serum. Contrast agents have been developed to enhance the
82 visualization of tumors by several imaging modalities including TVUS scanning [5-9]. Imaging
83 agents targeting $\alpha v\beta 3$ -integrins and vascular endothelial growth factor receptor 2 (VEGFR2)
84 have been developed for contrast enhanced ultrasound imaging [10, 11]. However, very few
85 reports are available on the ability of these targeted contrast agents in detecting OVCA at early
86 stage. Moreover, absence of a corresponding serum surrogate marker reduces the specificity and
87 sensitivity of these imaging agents. Thus additional imaging target(s) associated with malignant
88 transformation needs to be established and imaging agents needs to be developed to detect these
89 new imaging targets for early detection of OVCA with high specificity.

90 Inflammation has been suggested as a risk factor for malignant transformation [12].
91 Unresolved inflammation leads to hypoxic conditions accompanied by changes in inflammatory
92 cytokines including interleukin (IL)-16 [12, 13]. Ovulation is an inflammatory process which
93 exposes ovarian surface (at the site of ovulatory rupture) and fimbrial epithelium (the site of
94 reception of the ovulated ovum) to inflammatory factors including IL-16 secreted by immune
95 cells. Exposure of the ovary and tubal epithelium to inflammatory agents due to frequent
96 ovulation leads to the development of oxidative stress and longstanding unresolved oxidative
97 stress has been suggested to cause malignant transformation. On the other hand, expression of
98 IL-16 by the tumor epithelium and its serum levels has been reported to increase in association
99 with ovarian tumor development [14, 15]. Moreover, IL-16 has also been reported as a pro-
100 angiogenic factor [16] and may also be expressed by the endothelium of tumor associated

101 microvessels. Thus IL-16 represents a potential marker of early OVCA and IL-16 expressing
102 tissues in the ovary can be detected by ultrasound imaging provided an IL-16-targeted ultrasound
103 imaging agent can be developed.

104 Identification and access to patients with early stage OVCA are the significant barriers to
105 develop and test the efficacy of contrast enhancing imaging agents in detecting spontaneous
106 OVCA at early stage. Most of the available contrast agents were developed using rodents, thus,
107 are difficult to translate in human OVCA [17, 18, 11, 19]. Because, rodents do not develop
108 OVCA spontaneously and induced ovarian carcinoma in rodents are histopathologically not
109 similar to those of spontaneous OVCA in humans[20]. Recently, laying hens have been shown
110 to develop OVCA spontaneously with high incidence rates. Spontaneous OVCA in hens are
111 remarkably similar to human OVCA with regard to tumor histopathology and expression of
112 several molecular markers [21, 20, 22-26, 14]. Furthermore, methods for the imaging of hen
113 ovaries and ovarian tumors by TVUS scanning have been adapted [27-29]. Moreover, similar to
114 humans, expression of IL-16 by ovarian tumors has been reported to be increased in association
115 with tumor development and progression in hens, [14, 15]. Thus the laying hen represents a
116 highly innovative model to test the feasibility of IL-16-targeted imaging agents for the detection
117 of spontaneous OVCA at an early stage by non-invasive TVUS imaging. Therefore, the goal of
118 this study was to examine whether IL-16-targeted contrast agents enhance the intensity of
119 traditional TVUS imaging and improve the early detection of spontaneous ovarian tumors in
120 laying hens, a preclinical model of OVCA.

121

122

123

124 **2. Materials and Methods**

125 *2.1. Animals.* A flock of 3-4-years old commercial strains of White Leghorn laying hens (*Gallus*
126 *domesticus*) were maintained under standard poultry care and management and provided with
127 feed and water *ad libitum*. Egg-laying rates of the hens were recorded on a daily basis. Egg
128 laying rates in a hen is used as a relative indicator of ovulation rates in hens. The normal rate of
129 egg laying by a commercial laying hen is more than 250 eggs per year, and less than 50% of the
130 normal laying rate is considered a low egg-laying rate [27]. 150 hens with normal, low or
131 irregular egg-laying rates and those that stopped laying with no large preovulatory follicle, with
132 or without solid mass in the ovary and abdominal distention (a sign of possible ovarian tumor-
133 associated ascites) were selected for IL-16-targeted contrast enhanced imaging agents. The
134 incidence of ovarian cancer in laying hens of this age group was reported to be approximately
135 10% to 20% and is associated with low laying rates or complete cessation of egg laying [27, 21,
136 20]. All procedures were performed according to Institutional Animal Care and Use Committee
137 approved protocol.

138 *2.2. IL-16- targeted contrast enhanced ultrasound imaging agents.* IL-16-targeted imaging
139 agents were prepared by conjugating anti-chicken IL-16 antibodies with Targestar ® containing
140 microbubbles (Targeson, Inc San Diego, CA). Targestar SA is a targetable ultrasound contrast
141 agent coated with streptavidin. Biotinylated antibodies can be easily conjugated to the
142 microsphere surface, enabling target-specific retention for molecular imaging. The agent remains
143 acoustically active upto15 minutes. Agents are administered as an intravenous bolus injection.
144 Microbubbles preparation, ligand conjugation, characterization of labeled microbubbles and their
145 binding specificity of tumor tissues were similar to those reported earlier [10].

146 2.3. *Ultrasound imaging*

147 2.3.1. *Pre-contrast traditional transvaginal ultrasound (TVUS) imaging.* All hens were scanned
148 using an instrument equipped with a 1 to 7.5-MHz transvaginal transducer (MicroMaxx;
149 SonoSite, Inc, Bothell, WA) as reported previously with little modification [27, 29]. Hens were
150 immobilized and gently restrained by an assistant. Transmission gel was applied to the surface of
151 the transducer, the transducer was covered by a cover and to ensure uninterrupted conductance of
152 the sound waves, gel was reapplied to the covered probe. The transducer was inserted
153 approximately at a 30° angle to the body, 3 to 5 cm into the vagina and 2-dimensional (2D) gray
154 scale and pulsed Doppler sonography were performed. Young egg-laying hens (as the ovaries of
155 these hens contain more developing follicles compared to old hens) were used as standard
156 controls for mechanical adjustment to reveal and characterize the fully functional normal ovaries
157 of hens. The area of a tumor to be imaged was determined according to 3 conditions as reported
158 previously [27, 29]: (a) the whole tumor, if possible, should be seen on the image; (b) the
159 sectional plane should contain the solid part (wall, septa, and papillae) of the tumor; and (c) the
160 most vascularized area was selected. For normal ovaries, ovaries without any detectable tumor,
161 and atrophic ovaries, the region surrounding the ovary was scanned, and the transducer was
162 swept through the entire area for complete scanning of the ovary. Gray scale morphologic
163 evaluation of the ovarian mass was performed with attention to the number of preovulatory
164 follicles, the presence of abnormal-looking follicles, septations, papillary projections or solid
165 areas, and echogenicity. After morphologic evaluation, color Doppler mode was activated for
166 identification of vascular color signals. Once a vessel was identified on color Doppler imaging,
167 pulsed Doppler was activated to obtain a flow velocity waveform.

168 2.3.2. *Injection of IL-16-targeted contrast agents and contrast enhanced ultrasound imaging.*

169 Contrast imaging was performed following pre-contrast scanning. A preliminary experiment was

170 conducted with IL-16-targeted or isotype control microbubbles using 10 animals containing fully

171 functional ovaries to adjust the mechanical setup and determine the optimum dosage of

172 microbubbles. The dose of 10 μ L/kg body weight was found optimal for better resolution in the

173 preliminary experiment. Microbubbles containing contrast agents were prepared before injection.

174 Briefly, the vial containing the microbubble suspension was inverted and gently rotated to re-

175 suspend the microspheres completely. The suspension was transferred from the vial by an

176 injection syringe with a 19-gauge needle to a angiocatheter (small-vein infusion set, female luer,

177 12-in tubing, 25-gauge needle; Kawasumi Laboratories, Tampa, FL) containing 100 μ L of 0.9%

178 sodium chloride previously inserted into the left wing vein (brachial vein) of the hen and

179 followed by the reloading of 100 μ L of a 0.9% sodium chloride solution. The loading of the

180 sodium chloride solution before and after injection of microbubbles helped maintain the vascular

181 patency and airtight condition, in addition to flushing the bubbles from the hen's circulation.

182 The area imaged during pre-contrast scanning was imaged again after contrast

183 microbubble injection. Following injection of contrast agents and before post-contrast imaging,

184 time was allowed for microbubbles to bind with their targets and retention of bounded

185 microbubbles in the tumor as well as washing-out of unbound microbubbles. The timing of

186 contrast imaging was determined through an initial experiment using different time points

187 including 2, 5, 7 and 10min. Imaging after 7min of contrast agent injection was found optimum

188 with minimum background signals. Then a destructive pulse was delivered and images were

189 taken again. The difference in the intensity of ultrasound imaging between the images at 7min

190 after injection and images after the delivery of destructive pulse confirms that the signal acquired

191 after contrast agent injection was from microbubbles-bounded target tissue. For an individual
192 hen, the same imaging plane and same size of ROI was used for measuring the pre-contrast and
193 post-contrast intensity of ultrasound imaging. All images (screen shots) were archived digitally
194 in a still format as well as real-time clips on single-sided recordable digital video disks (DVD+R
195 format; Maxell Corporation of America, Fair Lawn, NJ) readable on a personal computer.

196 2.3.3. *Evaluation of the Effects of IL-16-Targeted Contrast Agents.* The effect of contrast agents
197 was evaluated visually during the examination and the enhancement of tumor detection by
198 contrast imaging was assessed afterward from reviewing the archived video clips. After review
199 of the complete clip the image containing the stroma of normal hens or containing the tumor
200 were selected and used as region of interest (ROI) for measuring the pre-contrast and post-
201 contrast intensity of ultrasound imaging. In normal hens, areas containing large developing
202 follicles were avoided during the selection of images containing the ROIs. The intensity of the
203 pixels in the selected area was measured using a computer-assisted software program
204 (MicroSuite version 5; Olympus Corporation, Tokyo, Japan) and expressed as arbitrary values.
205 The intensity of the ROI (sum of the arbitrary values from the pixels within the region of
206 interest) was measured from the pre-contrast and contrast image and expressed as the mean \pm SD
207 in 40,000 pixel area. The net contrast enhancement (CE = Ct-Cpt) was determined and the CE
208 ratio (CER) was calculated using the following equation: CER = (Ct-Cpt)/Cpt X 100% where
209 Cpt = values from ROI of pre-contrast image and Ct = values from ROI of contrast image. As
210 mentioned above, Ct is the difference between the intensity of ultrasound imaging from images
211 taken at 7min after injection of contrast agents and after the delivery of a destructive pulse.

212

213 2.4. *Ovarian gross morphologic evaluation.* All hens were euthanized after contrast imaging and
214 examined for the presence of a solid mass in the ovary as well as in any other organs, ascitic
215 fluid, preovulatory follicles, and atrophy of the ovary, as reported previously[21]. Gross
216 observation was compared with the sonographic evaluations and photographed. A normally
217 functional ovary had viable preovulatory follicles (more detailed information on hen ovarian
218 physiology has been published elsewhere [27, 21]), whereas no large follicles or visible lesions
219 were found in normal hens that stopped egg laying. Tumor staging was performed according to
220 the gross metastatic status as reported previously [21]. Briefly, early OVCA was characterized
221 by detectable formation of solid tumor limited to the ovary. Late stages of OVCA were
222 characterized by tumor metastasis to distant organs with moderate to extensive ascites.

223 2.5. *Histologic evaluation and immunohistochemical detection of ovarian IL-16-expressing
224 cells and microvessels.* Representative portions of a solid ovarian mass or the whole ovary (in
225 cases of atrophic or grossly normal-appearing ovaries) were divided into several blocks,
226 processed for paraffin or frozen sections, and stained with hematoxylin-eosin. Microscopic
227 tumor (if present) in any part of the ovary was detected by routine histologic examination with
228 hematoxylin-eosin staining, and tumor types were determined by light microscopy, as reported
229 previously [21].

230 After histopathologic examination, paraffin sections (5 μ m thick) of normal and
231 malignant ovaries of all stages and types were processed for routine immunohistochemistry to
232 assess the frequency of IL-16-expressing cells and microvessels using rabbit anti-chicken IL-16
233 polyclonal antibodies as reported earlier [14, 15]. The frequencies of IL-16-expressing cells and
234 microvessels were determined from the stroma of the ovarian tumors or ovarian stroma of

235 normal hens (excluding the follicular areas), as reported earlier [28, 30] using a light microscope
236 attached to digital imaging stereological software (MicroSuite version 5; Olympus Corporation)
237 with little modification. Briefly, immunostained slides were examined at low-power
238 magnification ($\times 10$ objective and $\times 10$ ocular) to identify the areas with maximum IL-16-
239 expressing cells or microvessels. Vessels with thick, regular, and complete muscular walls as
240 well as vessels with large lumina were excluded from the count, as reported previously[28]. In
241 each section, the 5 highly immunostained areas for IL-16 expressing cells or microvessels were
242 chosen and immunopositive cells or microvessels (with leaky, incomplete and thin vessel wall)
243 were counted. The number of immunopositive cells or microvessels in a $20,000\text{-}\mu\text{m}^2$ area was
244 counted at an $\times 40$ objective and $\times 10$ ocular magnification. The averages of these sections were
245 expressed as the number of immunopositive cells or microvessels in a $20,000\text{-}\mu\text{m}^2$ area of a
246 normal ovary or ovary with tumor. Tumor histology and immunohistochemical observations
247 were compared to the sonographic predictions.

248 2.6. *Statistical Analysis.* Descriptive statistics for imaging parameters were determined, and
249 statistical analysis was performed in SPSS version 15 (SPSS Inc, Chicago, IL). The differences
250 in the net intensities of ultrasound imaging and the frequencies of IL-16-expressing cells and
251 microvessels among normal hens or hens with early and late stage OVCA were analyzed by the
252 two-sample *t* test. The association between the intensity of ultrasound imaging and the frequency
253 IL-16-expressing cells or microvessels was examined by Pearson coefficient of correlations. $P <$
254 0.05 was considered significant. All reported P values are 2 sided.

255

256

257 **3. Results**

258 *3.1. Evaluation of non-invasive contrast enhanced ultrasound imaging.* In normal hens with
259 functional ovaries, multiple preovulatory follicles and small growing stromal follicles were
260 observed on pre-contrast and contrast imaging. Compared to pre-contrast ovaries, visualization
261 of solid ovarian masses with or without projected septa and papillary structures, accompanying
262 ascites, or both were enhanced remarkably in the ovaries of 23 hens. Of these 23 hens, 16 had
263 solid masses in the ovary together with profuse ascites and were predicted to have late-stage
264 OVCA (**Figure 1A-B and C-D**). In the remaining 7 hens, solid masses were limited to a part of
265 the ovary with no or little ascites, and they were provisionally categorized as early-stage OVCA
266 (**Figures 2A and B**). Compared with pre-contrast scanning, IL-16-targeted contrast enhanced
267 imaging improved the visualization of ovarian tumor masses in these 23 hens on gray scale
268 (**Figures 1 and 2**). All of these hens were categorized as "hens with suspected ovarian cancer".

269 All hens were euthanized following IL-16-targeted contrast imaging and sonographic
270 predictions as well as stages of the tumor were confirmed by gross examination of hens at
271 necropsy (**Figures 1E and 2D**). Ovarian morphology including ovarian follicles and their sizes,
272 oviducts, presence of solid mass in the ovary, levels of tumor metastasis, OVCA stages and
273 accompanying ascites, were recorded and tissues were processed as mentioned above. Tumor
274 types were determined by routine hematoxylin & eosin staining (H&E) of paraffin sections
275 (**Figure 1F**). Staging of ovarian tumors was performed as reported previously [21]. As observed
276 during targeted imaging, late stage OVCA (n = 16 hens including 7 serous, 6 endometrioid, 3
277 mucinous) was associated with moderate to profuse ascites and metastasized to peritoneal and
278 abdominal organs. Tumors in early stage OVCA (n = 7 including 4 serous, 2 endometrioid,
279 1mucinous) were limited to the ovary with no or little ascites.

280 Overall, mean signal intensity (mean \pm SD) of IL-16-targeted imaging in normal healthy
281 hens with low egg laying rates was $27.7 \times 10^5 \pm 3.3 \times 10^5$ which was 1.06 fold higher than the
282 pre-contrast signal intensities (**Figure 3**). However the difference was not statistically
283 significant. On the other hand, compared with pre-contrast ($39.9 \times 10^5 \pm 10.8 \times 10^5$) imaging,
284 the mean signal intensity increased significantly ($P < 0.05$) to $61.9 \times 10^5 \pm 21.2 \times 10^5$ in post-
285 contrast imaging in hens with tumor masses limited to the ovary (early stage). Thus, IL-16-
286 targeted contrast enhanced imaging increased ultrasound signal intensity to 1.55 fold in hens
287 with early stage OVCA (**Figure 3**). Similarly, in hens with late stage OVCA, the mean signal
288 intensity (mean \pm SD) increased significantly ($P < 0.001$) from $50.88 \times 10^5 \pm 10.37 \times 10^5$ in pre-
289 contrast imaging to $67.89 \times 10^5 \pm 10.86 \times 10^5$ in post-contrast imaging (**Figure 3**). Pre-as well
290 as post-contrast ultrasound signal intensities did not differ significantly among different
291 histological sub-types of ovarian tumors.

292

293 *3.2. Immunohistochemical detection of IL-16 expressing cells and microvessels.* IL-16-
294 expressing cells were detected in the stroma of normal or tumor-bearing ovaries and in the tumor
295 vicinity including spaces between tumor glands (**Figure 4, top panel**). A number of epithelial
296 cells (not all) in normal or tumor glands were also positive for IL-16 (**Figure 4, top panel B &**
297 **C**). Very few IL-16-expressing cells were seen in the ovarian stroma and the follicular theca layer
298 of normal healthy hens with low egg laying rates (**Figure 4, top panel A**). Compared with
299 normal hens many IL-16-expressing cells were localized in hens with OVCA (**Figure 4, top**
300 **panel B-C**). The frequency of stromal IL-16 expressing cells was significantly ($P < 0.0001$)
301 higher in hens with early stage OVCA (mean \pm SD = 21.85 ± 5.42 in $20,000 \mu\text{m}^2$ of tumor tissue)
302 than in normal hens (9.56 ± 4.87 in $20,000 \mu\text{m}^2$ of ovarian stromal tissue), and increased further

303 in hens with late stage of OVCA (28.56 ± 5.08 in $20,000 \mu\text{m}^2$ of tumor tissue) (**Figure 4, bottom**
304 **panel**).

305 IL-16-expressing microvessels were detected in both normal ovaries and ovaries with
306 tumor (**Figure 5, top panel A-C**). In normal ovaries, very few IL-16-expressing microvessels
307 were seen in ovarian stroma (**Figure 5, top panel A**). Compared with normal ovary, many IL-
308 16-expressing microvessels were localized in the stroma of ovaries with tumor (**Figure 5, top**
309 **panel B-C**). The frequencies of IL-16-expressing microvessels were significantly ($P < 0.0001$)
310 greater in hens with early stage OVCA (mean \pm SD = 7.0 ± 1.29 in $20,000 \mu\text{m}^2$ of tumor tissue)
311 than in normal hens (1.71 ± 0.49 in $20,000 \mu\text{m}^2$ of ovarian stromal tissue) and increased further
312 ($P < 0.0001$) in hens with late stage of OVCA (10.33 ± 2.38 in $20,000 \mu\text{m}^2$ of tumor tissue)
313 (**Figure 5, bottom panel**). Differences in the frequencies of IL-6-expressing microvessels were
314 not observed among different histological sub-types of malignant ovarian tumors in hens.

315 Increases in signal intensities due to IL-16-targeted contrast imaging were positively
316 correlated with the frequencies of IL-16-expressing microvessels in ovarian tumors at early stage
317 ($r = 0.46$) and late stage ($r = 0.70$). These results support the predictions of IL-16-targeted
318 contrast imaging that enhanced signal intensity due to the contrast imaging in hens with tumors
319 were due to the increased IL-16-expressing cells and microvessels in the ovaries with tumors.

320

321 **4. Discussion**

322 This study examined, for the first time, suitability of IL-16-targeted contrast agent, a newly
323 developed ultrasound imaging agent, in improving the *in vivo* visualization of ovarian tumors in
324 laying hens, a preclinical model of spontaneous OVCA. The results of this study demonstrated

325 that IL-16-targeted contrast imaging agents bounded with their targets expressed by ovarian
326 tumors at early and late stages in hens and enhanced the intensities of ultrasound imaging signals
327 from these tumors.

328 Increased expression of IL-16, a proinflammatory cytokine, has been reported to be
329 associated with the development and progression of several malignancies including OVCA [14,
330 15, 31]. In addition to stromal cells of the tumor, tumor epithelium has also been reported to
331 express IL-16 [14, 15]. Thus IL-16-expressing cells in ovarian tumors represent a potential target
332 for ultrasound imaging for non-invasive detection of OVCA at early stage provided a targeted
333 imaging agent is developed. In this study, compared with pre-contrast, IL-16-targeted contrast
334 enhanced imaging increased the ultrasound signal intensity remarkably both from hens with
335 ovarian tumors at early and late stages. These results suggest that IL-16-targeted contrast agents
336 bounded with their targets in the tumor tissues. In addition, as reported earlier for humans and
337 hens [14, 15], this study also showed significant increase in the frequency of IL-16-expressing
338 cells in hens with early and late OVCA than normal hens. Thus, higher signal intensities in hens
339 with early and late stage OVCA than normal hens may, in part, due to the increased frequency of
340 targets (IL-16-expressing cells) in OVCA hens bounded with their ligands (IL-16-targeted
341 imaging agents).

342 IL-16 is a proangiogenic factor suggested to stimulate tumor-associated angiogenesis
343 [16]. Furthermore, the frequency of IL-16-expressing cells was reported to be positively
344 correlated with the frequencies of smooth muscle actin (SMA)-expressing microvessels [14]
345 during OVCA development and progression in hens. In this study, endothelial cells of
346 microvessels expressed IL-16. Furthermore, this study also showed that the density of IL-16-

347 expressing microvessels increased significantly with the development of OVCA and increased
348 further as the tumor progressed to late stages. The frequencies of tumor associated microvessels
349 expressing $\alpha_v\beta_3$ -integrins and VEGFR-2 have also been suggested to increase contrast enhanced
350 ultrasound signal intensities [32, 33]. Thus, in addition to malignant cells, increase in the
351 frequency of IL-16-expressing microvessel might also be a reason for the increased signal
352 intensities during contrast enhanced imaging in hens with OVCA.

353 The results observed in the current study have, from translational point of view, some
354 exceptional aspects. *First*, most of the contrast agents so far developed including two most
355 extensively studies agents $\alpha_v\beta_3$ -integrins and VEGFR-2, have limited success as expression of
356 these targets were mainly limited to the blood vessels. Moreover, no corresponding serum
357 markers of these imaging targets specific to OVCA have been established making their
358 application difficult for early detection of OVCA. In contrast, in addition to the expression of IL-
359 16 by the tumor epithelium and the microvessels, IL-16 is also secreted into the circulation.
360 Serum levels of IL-16 have been reported to be increased significantly in association with OVCA
361 development and progression [14, 15]. Thus, serum IL-16 levels offers a potential marker to be
362 used in conjunction with IL-16-targeted contrast enhanced ultrasound imaging for the detection
363 of OVCA at early stage. *Second*, most of the previous studies used rodent models with induced
364 tumors. On the other hand, this study used laying hens, the only widely available and easily
365 accessible spontaneous model of OVCA. Rodents do not develop OVCA spontaneously and the
366 histopathology of induced OVCA is not similar to those of spontaneous OVCA. Moreover,
367 anatomical differences in the location of induced rodent models (subcutaneous tumor) compared
368 with deeper tissue like the ovary may also affect on the transduction of ultrasound signals as well
369 as the behavior of contrast agents. Thus information on the binding ability and detection of

370 spontaneous OVCA by contrast agents (as seen for IL-16) is essential. *Third*, chickens are easy
371 to access to test and develop targeted imaging agents as well as anti-OVCA drugs for the
372 detection and treatment of spontaneous OVCA. Moreover, because of the lower cost of hens, this
373 model is also suitable for toxicological studies of newly developed imaging agent or therapeutic
374 in a cost-effective way. Presently, studies with hens are ongoing in which animals are being
375 monitored prospectively with IL-16-targeted contrast agents together with serum IL-16 levels to
376 detect spontaneous ovarian tumor development at relatively earlier stages. This study has also
377 some limitations. We did not use animals with benign ovarian tumors. Small sample size
378 specially the number of hens with ovarian tumors may also be a limitation of this study.

379 **5. Conclusion.** Overall, the results of the present study suggest that the IL-16-targeted contrast
380 agents bind with their targets expressed by the spontaneous ovarian tumors in hens and enhance
381 the visualization of tumors at early and late stages. This study also suggests that laying hens offer
382 a new avenue for testing and development of new contrast agents and targeted anti-angiogenic
383 therapeutics.

503 **FIGURE LEGENDS**

504 FIGURE 1: Enhancement of signal intensity of ultrasound imaging of hen ovarian tumors by IL-
505 16-targeted contrast agents. A) Case 1: Pre-contrast gray scale ultrasonogram of a hen ovary
506 showing solid mass (dotted lines) with septa and accompanied ascites (AS). B) Post-contrast
507 gray scale ovarian sonogram of the same hen showing enhanced visualization of the solid tumor
508 mass. C) Case-2: Pre-contrast gray scale sonogram depicting a suspected ovarian mass (dotted
509 lines) in another hen. D) Gray scale sonogram of the same ovary (shown in C), depicting solid
510 tumor mass with enhanced signal intensity after the injection of targeted imaging agents. E)
511 Gross presentation confirmed the imaging prediction of an ovarian tumor (shown in C-D,
512 appeared as cauliflower –shaped, yellow circled). F) Histological examination showed a serous
513 malignant tumor with cells containing large pleomorphic nuclei surrounded by a sheath of
514 fibromuscular tissues. H & E staining.

515 FIGURE 2: Detection of spontaneous ovarian tumors at early stage in hens by IL-16-targeted
516 contrast enhanced ultrasound imaging. A) Pre-contrast ovarian sonogram showing low intensity
517 of ultrasound imaging. Presence of tumor-related solid mass in the ovary is inconclusive. B-C)
518 Corresponding contrast enhanced sonogram with enhanced visualization of ultrasound imaging
519 at 5min and 7min after the injection of contrast agents, respectively, suggesting the presence of a
520 small solid mass (yellow dotted lines) in the ovary. D) Gross morphology shows the presence of
521 a tissue mass (yellow dotted line) limited to a part of the ovary accompanied with a little ascites.

522 FIGURE 3: Changes in the signal intensity of ultrasound imaging by IL-16-targeted contrast
523 agent in the ovary of laying hens with or without ovarian cancer (OVCA). Compared with pre-
524 contrast imaging, IL-16-targeted contrast agents enhanced the intensities of ultrasound imaging

525 significantly in hens with early stage OVCA as well as in late stage OVCA. However, significant
526 differences were not observed between the pre- and post-contrast imaging in healthy hens.
527 Different letters denote significant differences in the intensities of ultrasound imaging between
528 the pre- contrast and post-contrast imaging within the same group including hens with normal
529 ovaries and with early and late stages of OVCA.

530 FIGURE 4: Immunohistochemical localization of IL-16-expressing cells in the ovaries of hens
531 predicted to be normal or cancerous by IL-16-targeted contrast enhanced ultrasound imaging.
532 **Top panel:** A) Section of a normal hen ovary showing few IL-16 expressing cells in the ovarian
533 stroma (S) and the follicular (F) theca (T). B-C) Sections of tumor ovaries at early (B) and late
534 (C) stages of OVCA. Compared with normal ovary, many IL-16 expressing cells are seen in
535 OVCA hens. S= stroma, Arrows indicate the examples of IL-16 expressing cells. **Bottom panel:**
536 Compared with normal, the frequency of IL-16 expressing cells increased significantly
537 ($P<0.001$) with tumor development and progression to late stages. Bars with different letters
538 indicate significant differences in the frequencies of IL-16-expressing cells among hens with
539 normal, early stage and late stage OVCA.

540 FIGURE 5: Expression of IL-16 by microvessels in the ovaries of hens with or without ovarian
541 tumors scanned by targeted ultrasound imaging. **Top panel:** A) Section of a normal ovary
542 showing few IL-16-expressing microvessels in the stroma (S). B and C) Sections of malignant
543 ovaries at early (B) and late (C) stages of OVCA. Compared with normal (A), more IL-16-
544 expressing microvessels are seen in OVCA hens. S= stroma, Arrows indicate examples of IL-16-
545 -expressing microvessels vessels. **Bottom panel:** Compared with normal, the frequency of IL-
546 16-expressing microvessels was significantly ($P<0.001$) high in OVCA hens at early and late

547 stages. Bars with different letters indicate significant differences in the frequencies of IL-16-
548 expressing microvessels among hens with normal, early stage and late stage OVCA.
